A simple circuit is solved and power absorbed or supplied by each element is determined. KCL as well as Ohm's law are used in solving the circuit. positive sign convention is used in determining element powers. It is shown and discussed how a source, here current source, can be neither absorbing or supplying power.

A circuit breaker in series before the parallel branches can prevent overloads by automatically opening the circuit. A 15 A circuit operating at 120 V consumes 1,800 W of total power. $P = VI = (120 \text{ V})(15 \text{ A}) = 1,800 \text{ W}$. Total power in a parallel circuit is the sum of the power consumed on the individual branches.

Solve the circuit by mesh analysis and find the current and the voltage across . Solution Mesh Analysis. There are four meshes in the circuit. So, we need to assign four mesh currents. It is better to have all the mesh currents loop in the same direction (usually clockwise) to prevent errors when writing out the equations. Update 2019/07/27

Mesh Analysis (Current Analysis) Problem - Solved Problems

Mesh current Analysis provide a procedure for electric circuit analysis using mesh current as the circuit variable. The mesh analysis makes use of Kirchhoff's Voltage Law as a basic key to analyze the circuit. In contrast to Nodal analysis, it uses loop current as a variable rather than element current, so it reduces the number of equations and complexity.
